Haematological Malignancy Research Network: first report to the clinical network

Background

The Haematological Malignancy Research Network (HMRN) was established to provide robust, generalizable data to inform clinical practice and research; it is a collaborative project between the clinical network, the Haematological Malignancy Diagnostic Service (HMDS) and the Epidemiology & Cancer Statistics Unit (ECSG) at the University of York. Since September 2004, all new diagnoses made by HMDS from patients across the Yorkshire and Humber & Yorkshire Coast Cancer Networks who had no prior record of a haematological malignancy have been included in HMRN. For these patients, demographic and clinical data have been abstracted from their medical records by ECSG research nurses, and these data have been added to the diagnostic information obtained from HMDS. This initial report is based on 10,729 diagnoses from 10,306 patients newly diagnosed in the first five years of HMRN: 1st September 2004 to 31st August 2009.

Methods & Interpretation

Death certificate data for all patients is obtained from the NHS Central Register (NHSCR) and the analysis presented here includes all deaths up to the 31st May 2011. Overall survival and 1-year survival have been calculated using time to event analyses, including Kaplan-Meier and Cox proportional hazard regression. Relative survival, which takes into account the background mortality rate in the general population, has also been estimated.

Comparisons between hospitals and MDTs were made using the organisation (hospital or MDT) with the largest number of patients as the baseline: Leeds Teaching Hospitals in the case of the former and Humber Yorkshire Coast Cancer Network (HYCCN) in the case of the latter. Risk estimates are reported for hospitals with 10 or more diagnoses.

To adjust for differences in case-mix, diagnostic age and sex were routinely included in the models. These adjusted hazard ratios (HR) and 95% confidence intervals (95% CI) are reported alongside the unadjusted estimates. Where appropriate, further adjustments were

made for prognostic factors, for example International Prognostic Index (IPI) for diffuse large B-cell lymphoma (DLBCL). More information about the data presented is provided in the figure overleaf. For hospitals where only one patient was diagnosed or recorded, information has been removed from the rows to protect patient confidentiality; hence some tables may not sum to the total presented. With respect to interpretation, an important caveat is that due to the large number of comparisons made, some associations may have occurred by chance alone. Future reports will allow the use of different statistical techniques as the number of diagnoses will increase, thus avoiding the need to make comparisons to one institution.

A HR of 1.91 (1.29 – 2.82) means patients are nearly twice as likely to die compared to the baseline group. However, when the analysis is repeated taking into account differences in case-mix by hospital (age at diagnosis and sex) there is no longer any difference in survival: 1.15 (0.77 - 1.70).

Table 42: AML Overall Survival by Diagnostic Hospital and Multi-Disciplinary Team

	Diagnostic N (%)	Age at Diagnosis (years) Median (range)	Alive N (%)	Dead N (%)	HR (95%CI) ¹	Adjusted HR (95%CI) ²
Total	717 (100)	68.8 (0.2 - 97.2)	155 (21.6)	562 (78.4)	-	-
Hospital:						
Airedale	36 (5.0)	73.4 (0.2 - 91.4)	3 (8.3)	33 (91.7)	1.91 (1.29 - 2.82)	1.15 (0.77 - 1.70)
Bradford Royal	59 (8.2)	70.5 (17.5 - 89.3)	12 (20.3)	47 (79.7)	1.60 (1.14 - 2.25)	1.27 (0.90 - 1.79)
Calderdale & Huddersfield	58 (8.1)	71.2 (24.6 - 90.9)	8 (13.8)	50 (86.2)	1.56 (1.11 - 2.18)	1.04 (0.74 - 1.46)

¹Hazard Ratio (HR) & 95% Confidence Intervals (95%CI), ²adjusted for age and sex. ³Hull & York Yorkshire Coastline Cancer Network (HYCCN)

Baseline group

Hazard ratios (HR) are only reported for groups with 10 or more patients.

Baseline group

Statistical significance can be inferred from the confidence intervals. If the 95% Confidence Intervals do not include 1, the effect is statistically significant at the 5% level ($p<0.05$)

A HR of 0.77 (0.62 - 0.95) means that there is a statistically significant ($p<0.05$) increase in survival by 23% for patients in the Leeds MDT compared to the baseline group - HYCCN. However, when the analysis is repeated taking into account differences in case-mix by MDT (age at diagnosis and sex) there are no longer any differences: 0.98 (0.79 - 1.22).

HMRN First Report to the Clinical Network

Review by Audit Committee

The HMRN audit committee reviewed this report on the 9th of March 2012, the purpose being to determine:

1. *That the data was valid and presented in a way that could reasonably be interpreted by all members of the network and the public.*
2. *To identify any areas of concern with regard to clinical practice that would require further investigation.*
3. *To agree the communication policy for the report.*

With respect to the first objective the committee were impressed by the depth and quality of the information. They were satisfied that the processes for collection and analysis of the data were robust and presented in a form that could easily be interpreted by readers.

To identify areas of clinical concern the committee reviewed all of the comparative data presented in the report. The committee received support in their interpretation of the data from members of staff at the Epidemiology and Cancer Statistics Group (ECSG). They were particularly mindful of the fact that when analysing such large numbers of variables it was highly likely that the 95% confidence intervals used would lead to a number of "statistically significant" results being produced that were due to chance rather than real variances.

Overall the committee were impressed by the consistency of performance between different units and MDTs across the spectrum of haematological malignancies. They felt that this reflected the effective MDT structure, the high quality diagnostic service and robust treatment guidelines in operation across the clinical network.

The committee identified only 2 areas of potential variation that they considered may required further investigation. All other identified variances were felt to be of such a minor degree or to relate to such small numbers that they were almost certainly related to chance. The 2 areas identified were DLBCL and Myeloma.

An initial inspection of DLBCL data appeared to demonstrate comparatively poor performance at Leeds Teaching Hospitals. However, further analysis revealed that the result could be explained by the high proportion of patients with CNS involvement that were treated in LTH in accordance with network guidelines. These patients have a particularly poor outcome, and when this was taken into account no evidence of significant variation in outcomes remained. The committee accepted this explanation and did not consider any further action was required.

The committee felt that the myeloma analysis demonstrated significant variation in outcome with respect to patients diagnosed in Pontefract and to a lesser extent in Scunthorpe. In both units the poor performance appeared to have no obvious explanation. The committee were advised that a more detailed myeloma audit, which would provide a greater level of detail on prognostic factors and therapy across the network, was already being undertaken. The committee agreed that a more detailed analysis was the appropriate action; and also advised that because of the large apparent variance, the Mid Yorkshire MDT should review the cases treated at Pontefract. It was agreed that the identity of the patients would be made available to the MDT for this purpose.

The committee agreed that the report should be disseminated widely to both commissioners and provider organisations across the network and that it would be made available on the public area of the HMRN website. It was agreed that all network clinicians would be informed prior to circulation.
